

Basic PHP Syntax

Explore fundamental PHP programming concepts focusing on arrays and string manipulation with regular expressions.

Arrays

Dynamic data structures for storing multiple values

Strings & RegExp

Text processing and pattern matching techniques

Course: CS380

Arrays

Create Empty Array

```
$name = array();
```

Create with Values

```
$name = array(value0, value1, ..., valueN);
```

Access Elements

```
$name[index] // get value  
$name[index] = value; // set value
```

Practical Example

```
$a = array(); // empty array (length 0)  
$a[0] = 23; // stores 23 at index 0 (length 1)  
$a2 = array("some", "strings", "in", "an", "array");  
$a2[] = "Ooh!"; // append to end (at index 5)
```

- ❏ **Key Features:** Use bracket notation without index to append. Element types can be mixed within the same array.

Array Functions

PHP provides powerful built-in functions for array manipulation and processing.

Function Name(s)	Description
<u>count</u>	Number of elements in the array
<u>print_r</u>	Print array's contents
<u>array_pop</u> , <u>array_push</u> , <u>array_shift</u> , <u>array_unshift</u>	Using array as a stack/queue
<u>in_array</u> , <u>array_search</u> , <u>array_reverse</u> , <u>sort</u> , <u>rsort</u> , <u>shuffle</u>	Searching and reordering
<u>array_fill</u> , <u>array_merge</u> , <u>array_intersect</u> , <u>array_diff</u> , <u>array_slice</u> , <u>range</u>	Creating, filling, filtering
<u>array_sum</u> , <u>array_product</u> , <u>array_unique</u> , <u>array_filter</u> , <u>array_reduce</u>	Processing elements

Array Function Example

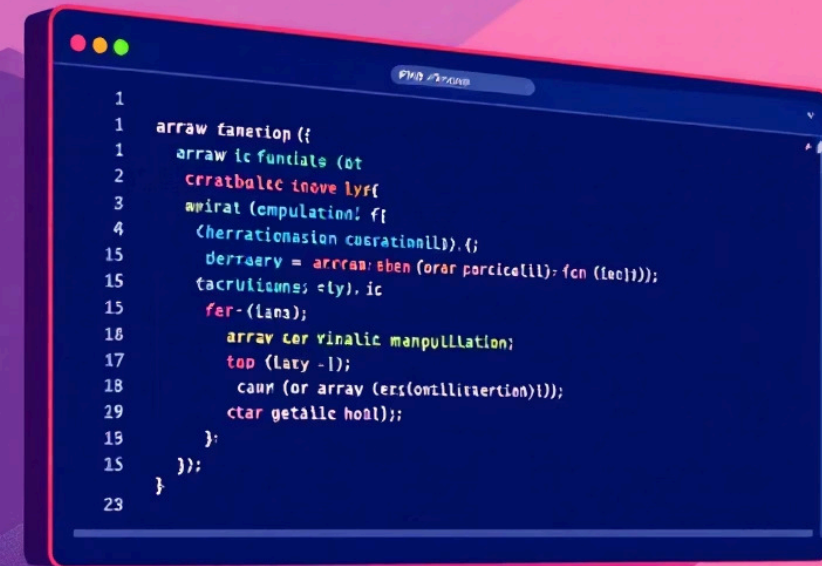

```
$tas = array("MD", "BH", "KK", "HM", "JP");  
for ($i = 0; $i < count($tas); $i++) {  
    $tas[$i] = strtolower($tas[$i]);  
}  
$morgan = array_shift($tas); // Remove first element  
array_pop($tas);           // Remove last element  
array_push($tas, "ms");    // Add to end  
array_reverse($tas);       // Reverse order  
sort($tas);                // Sort alphabetically  
$best = array_slice($tas, 1, 2); // Extract subset
```

Stack/Queue Operations

Use [push/pop](#) for stack behavior, [shift/unshift](#) for queue operations.

Versatile Collection

PHP arrays replace multiple Java collections: list, stack, queue, set, and map functionality.

foreach Loop

Syntax

1

```
foreach ($array as $variableName) {  
    // process each element  
}
```

2

Cleaner Code

More readable than traditional for loops when processing all elements

Comparison Example

```
$fellowship = array("Frodo", "Sam", "Gandalf", "Strider", "Gimli", "Legolas", "Boromir");
```

```
// Traditional for loop
```

```
print "The fellowship of the ring members are:\n";  
for ($i = 0; $i < count($fellowship); $i++) {  
    print "{$fellowship[$i]}\n";  
}
```

```
// foreach loop - cleaner!
```

```
print "The fellowship of the ring members are:\n";  
foreach ($fellowship as $fellow) {  
    print "$fellow\n";  
}
```

📌 **Best Practice:** Use foreach when you need to process every element in an array - it's more readable and less error-prone.

Multidimensional Arrays

Arrays can contain other arrays, creating nested data structures for complex data organization.

Numeric Indices

1

```
<?php $AmazonProducts = array(
    array("BOOK", "Books", 50),
    array("DVDs", "Movies", 15),
    array("CDs", "Music", 20)
);

for ($row = 0; $row < 3; $row++) {
    for ($column = 0; $column < 3; $column++) { ?>
        <p>
```

Accessing Elements

2

Use `$array[row][column]` notation to access elements in 2D arrays.
Perfect for representing tables, matrices, or structured data with rows and columns.

Associative Multidimensional Arrays

Use named keys instead of numeric indices for more readable and maintainable code.

```
<?php $AmazonProducts = array(
    array("Code" => "BOOK", "Description" => "Books", "Price" => 50),
    array("Code" => "DVDs", "Description" => "Movies", "Price" => 15),
    array("Code" => "CDs", "Description" => "Music", "Price" => 20)
);

for ($row = 0; $row < 3; $row++) { ?>
    <p>
```

Named Keys

Use descriptive names like "Code", "Description" instead of numbers

Database-like

Perfect for representing structured data similar to database records

String Compare Functions

PHP provides powerful functions for string comparison and manipulation operations.

Name	Function
<u>strcmp</u>	compareTo equivalent
<u>strstr, strchr</u>	Find string/char within a string
<u>strpos</u>	Find numerical position of string
<u>str_replace, substr_replace</u>	Replace string content

Comparison Types

- Partial matches
- Case-sensitive options

Case-Insensitive

Use [strcasecmp](#) for case-insensitive comparisons

String Function Examples

01

String Replacement

```
$offensive = array("badword1", "badword2");  
$feedback = str_replace($offensive, "%!@*",  
$feedback);
```

Clean user input by replacing inappropriate content

02

Position Finding

```
$test = "Hello World!\n";  
print strpos($test, "o"); // Returns 4  
print strpos($test, "o", 5); // Start search from  
position 5
```

Locate specific characters or substrings within text

03

Conditional Routing

```
$toaddress = "feedback@example.com";  
if(strpos($feedback, "shop"))  
    $toaddress = "shop@example.com";  
else if(strpos($feedback, "delivery"))  
    $toaddress = "fulfillment@example.com";
```

Route messages based on content keywords

Regular Expressions

Regular expressions are powerful patterns for matching and manipulating text. PHP supports both POSIX and Perl-style regex.

1

Character Classes

```
[a-z]at // cat, rat, bat...  
[aeiou] // any vowel  
[a-zA-Z] // any letter  
[^a-z] // NOT lowercase letter
```

2

Predefined Classes

```
[:alnum:]+ // at least one alphanumeric char
```

3

Quantifiers

```
(very)*large // large, very large, very very large...  
(very){1,3} // "very" appears 1 to 3 times
```

4

Anchors

```
^bob // "bob" at the beginning  
com$ // "com" at the end
```

- ❑ **Pattern Matching:** Regular expressions define patterns to find, validate, or replace specific text sequences within strings.
